

Modern color theory

CS 48N, Winter 2011

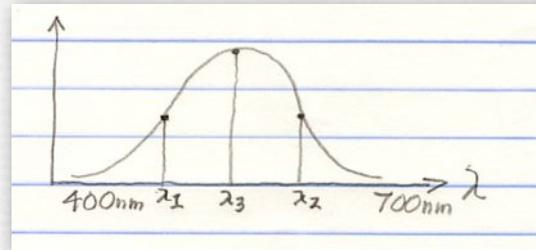

Marc Levoy
Computer Science Department
Stanford University

Thomas Young (1773-1829)

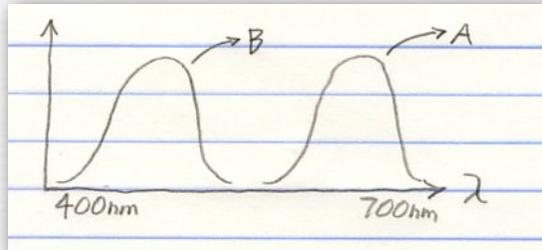

Monochromats (contents of whiteboard)

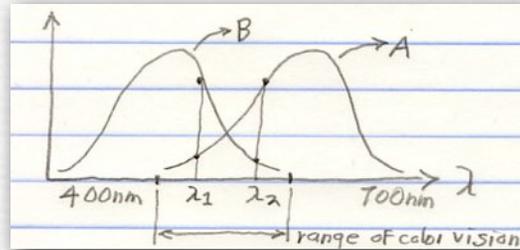

1

1. organisms having only one kind of retinal receptor cannot distinguish changes in intensity from changes in wavelength, hence they have no *color discrimination*
 - for example a unit amount of λ_1 versus λ_2 above
 - or a unit amount of λ_1 versus half as much of λ_3 (assuming the sensitivity to λ_3 is twice the response to λ_1)

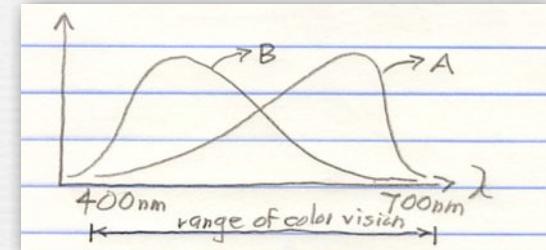

Dichromats (contents of whiteboard)

2

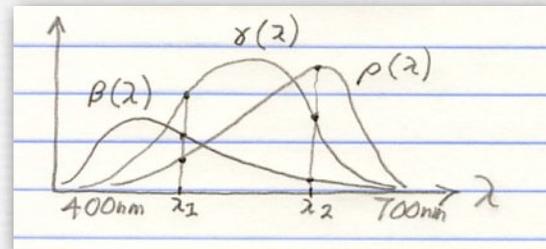

3

4

2. this organism can discriminate a response in the range wavelengths covered by A versus B, but cannot discriminate within those ranges
3. this organism has color discrimination over the range of wavelengths shown
 - for each wavelength within this range, the ratio of responses of receptors A and B is unique; hence the organism can identify which wavelength (e.g. λ_1 or λ_2) it's looking at
4. this organism has a larger range of color vision

Trichromats (contents of whiteboard)

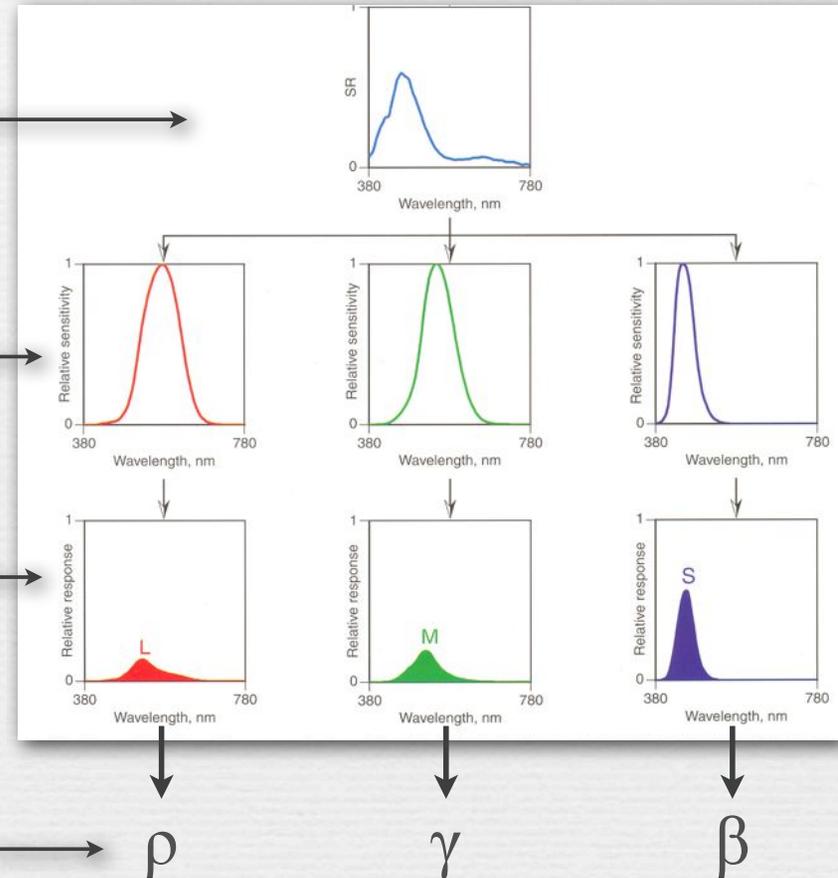

5

5. humans can discriminate wavelengths from 400nm to 700nm
 - we can also discriminate mixtures of wavelengths that dichromats cannot; this will become clearer later
- ♦ at the retinal level, our response to light is linear
 - a. if the response to a unit stimulus at λ_1 is $(\rho_1, \gamma_1, \beta_1)$, and to a unit stimulus at λ_2 is $(\rho_2, \gamma_2, \beta_2)$, then the response to a superposition of stimuli λ_1 and λ_2 is $(\rho_1 + \rho_2, \gamma_1 + \gamma_2, \beta_1 + \beta_2)$
 - b. the response to n units of a stimulus at λ_1 is $(n \rho_1, n \gamma_1, n \beta_1)$
 - c. a system that obeys *superposition* (a) and *scaling* (b) is *linear*

Human response to an arbitrary stimulus

(Berns)

spectrum of stimulus arriving
in one small area on retina
 \times
spectral sensitivity of each
type of cone (L,M,S)
 $=$
multiply wavelength-by-
wavelength to get response spectra
 \int
integrate over wavelengths to get
total response for that type of cone

♦ output is three numbers (ρ , γ , β) per area on retina

Human response to an arbitrary stimulus

(Berns)

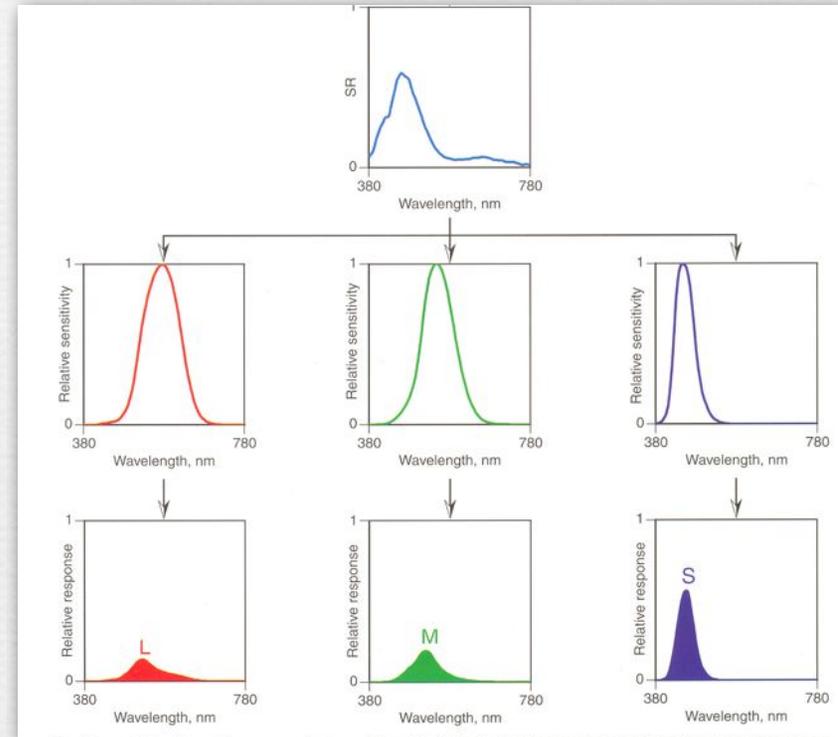

- ♦ stated another way, given a stimulus spectrum $L_e(\lambda)$, the human response to it (ρ, γ, β) are the integrals over all visible wavelengths of our responses

$$L_e(\lambda) \rho(\lambda),$$

$$L_e(\lambda) \gamma(\lambda),$$

$$L_e(\lambda) \beta(\lambda)$$

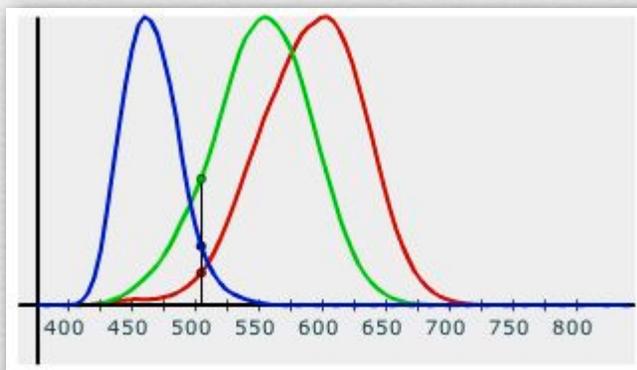

to each constituent wavelength λ , i.e.

$$(\rho, \gamma, \beta) = \left(\int_{400 \text{ nm}}^{700 \text{ nm}} L_e(\lambda) \rho(\lambda) d\lambda, \int_{400 \text{ nm}}^{700 \text{ nm}} L_e(\lambda) \gamma(\lambda) d\lambda, \int_{400 \text{ nm}}^{700 \text{ nm}} L_e(\lambda) \beta(\lambda) d\lambda \right)$$

Human 3D colorspace

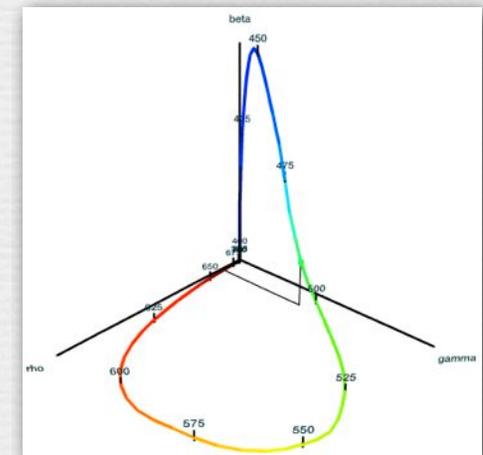

- ◆ the three types of cones in our retina (Long, Medium, Short wavelength) define the axes of a three-dimensional space
- ◆ our response to any stimulus spectrum can be summarized by three numbers (ρ , γ , β) and plotted as a point in this space
- ◆ our responses to all visible single-wavelength spectra (a.k.a. pure wavelengths λ , i.e. positions along the rainbow), if connected together, form a curve in this space, called the *locus of spectral colors*; the sequence of (ρ , γ , β) numbers form the *tristimulus sensitivity functions* $\rho(\lambda)$, $\gamma(\lambda)$, and $\beta(\lambda)$

sensitivity functions

Properties of human 3D colorspace (1 of 2) (contents of whiteboard)

1

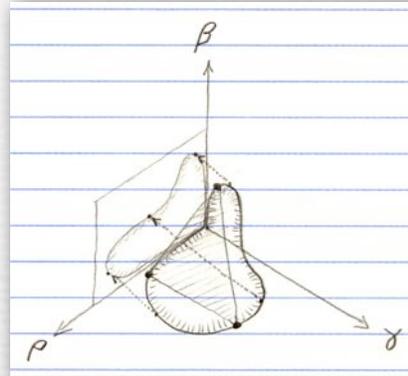

2

3

1. our response to any mixture ($\Sigma = 1$) of two pure wavelengths falls on a line connecting the responses to each wavelength
2. our response to any mixture ($\Sigma = 1$) of three pure wavelengths falls on a triangle connecting the responses to each wavelength; our response to any mixture ($\Sigma \leq 1$) of three pure wavelengths falls in a tetrahedron defined by this triangle and the origin
3. our responses to all possible mixtures ($\Sigma \leq 1$) of all visible wavelengths forms an irregular volume called the *gamut of perceivable colors*, equal to the convex hull of the spectral locus

Properties of human 3D colorspace (2 of 2) (contents of whiteboard)

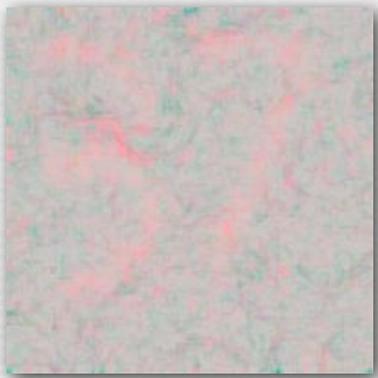

4

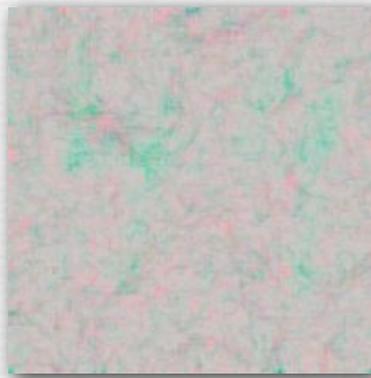

4. to a deuteranope - a color-blind person who is missing their medium-wavelength receptor, i.e. their gamma receptor - this diagram is squashed into the rectangle shown above on the rho-beta plane
- as a result, spectra whose (ρ, γ, β) responses lie along the dotted lines cannot be distinguished; they will appear as the same color, i.e. as metamers
 - by a similar argument, many spectra distinguishable to pentachromats (e.g. Mallard ducks) are indistinguishable to trichromats (humans)

Color blindness

37?

49?

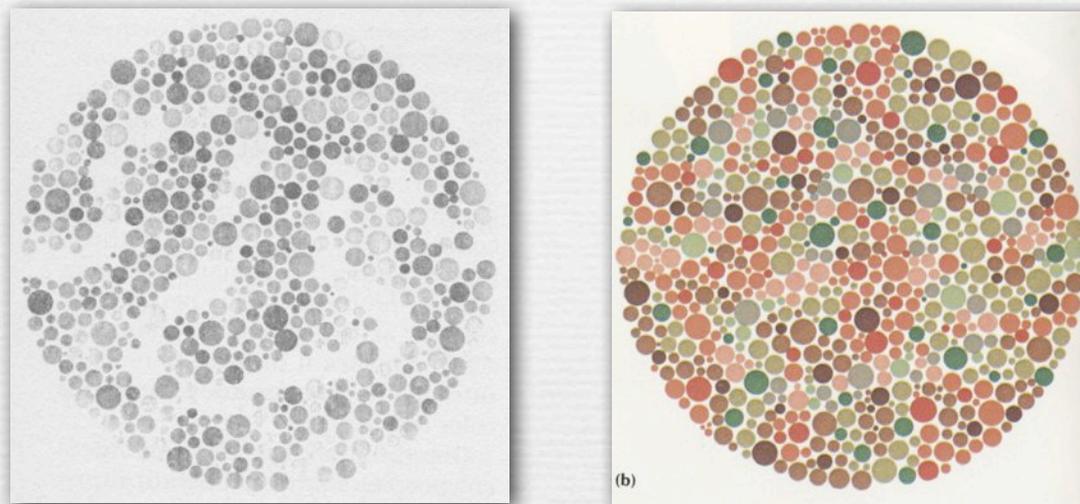

56?

(wikipedia)

- ◆ protanopia (1% of males)
- ◆ deuteranopia (1% of males)
- ◆ tritanopia (< 1% of both genders)
- ◆ protanomaly (1% of males)
- ◆ deuteranomaly (6% of males)
- ◆ tritanomaly (< 1% of both genders)

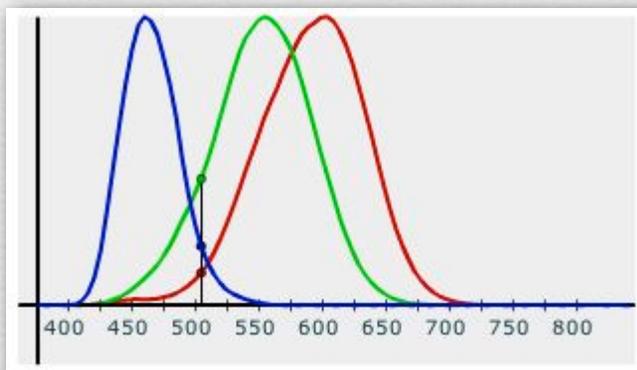

The advantage of being color blind

- ◆ the maze (at left) is recreated (at right) using subtle intensity differences, but overridden by stronger red-green color differences
- ◆ only a deuteranope can see the maze at right

Human 3D colorspace

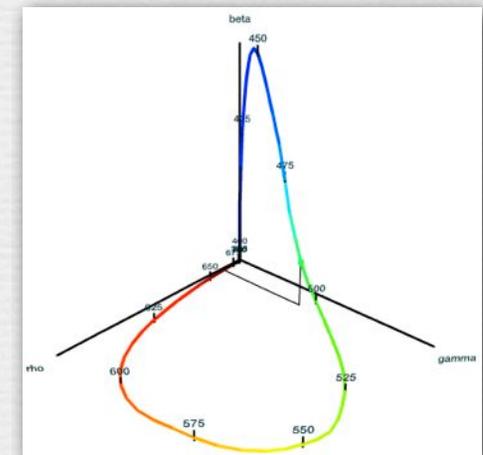

- ◆ the three types of cones in our retina (Long, Medium, Short wavelength) define the axes of a three-dimensional space
- ◆ our response to any stimulus spectrum can be summarized by three numbers (ρ , γ , β) and plotted as a point in this space
- ◆ our responses to all visible single-wavelength spectra (a.k.a. pure wavelengths λ , i.e. positions along the rainbow), if connected together, form a curve in this space, called the *locus of spectral colors*; the sequence of (ρ , γ , β) numbers form the *tristimulus sensitivity functions* $\rho(\lambda)$, $\gamma(\lambda)$, and $\beta(\lambda)$

sensitivity functions

Maxwell's color matching experiment

- ◆ Maxwell actually used a slightly different procedure
 - see <http://www.handprint.com/HP/WCL/color6.html> for details
 - the procedure below is used in modern versions of the experiment

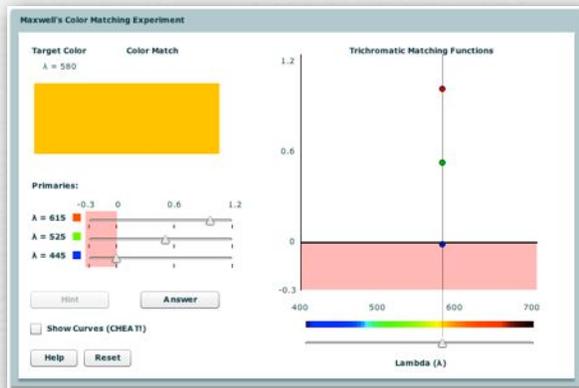

(FLASH DEMO)

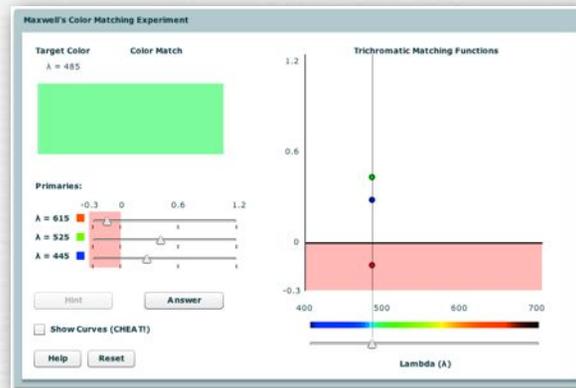

<http://graphics.stanford.edu/courses/cs178/applets/colormatching.html>

Maxwell's color matching experiment

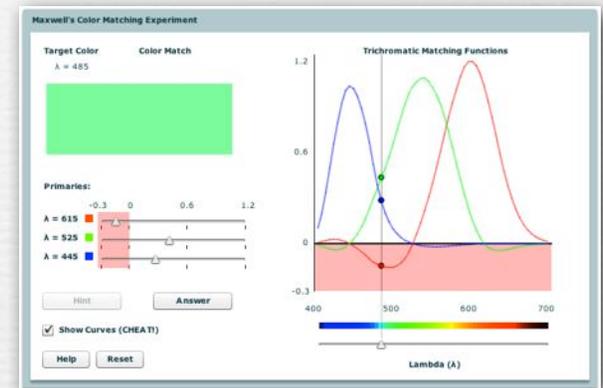

(summary of live demo)

1

2

3

1. given a stimulus wavelength, the amount of each primary required to match it is given by three numbers (r, g, b)
2. some stimuli cannot be matched unless first desaturated by adding a primary to it before matching; the amount added is denoted by negative values of r , g , or b
3. the sequence of $(\bar{r}, \bar{g}, \bar{b})$ values, some negative, required to match the locus of spectral colors across all λ , form the *trichromatic matching functions* $r(\lambda)$, $g(\lambda)$, and $b(\lambda)$ for a particular set of 3 primaries

Young-Helmholtz trichromatic theory

Thomas Young
(1773-1829)

James Clerk Maxwell
(c. 1860)

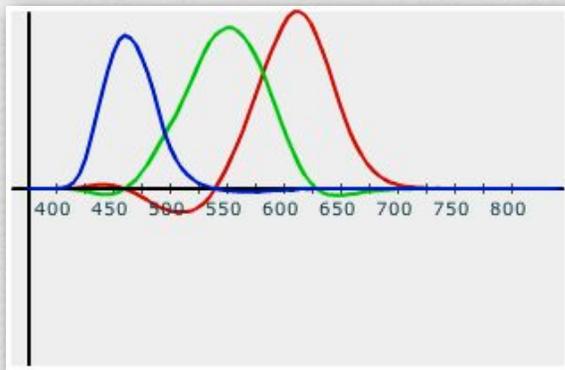

Hermann von Helmholtz
(1821-1894)

- ◆ spectra can be visually matched using mixtures of *primary colors*; such matches are called *metamers*
- ◆ due to the linearity of human retinal response, given a stimulus spectrum $L_e(\lambda)$, the amounts of each primary R, G, B required to match it, for any particular choice of 3 primaries, are the integrals over all visible wavelengths of the amounts $r(\lambda)$, $g(\lambda)$, and $b(\lambda)$ required to match each constituent wavelength λ , *i.e.*

$$(R, G, B) = \left(\int_{400\text{nm}}^{700\text{nm}} L_e(\lambda) \bar{r}(\lambda) d\lambda, \int_{400\text{nm}}^{700\text{nm}} L_e(\lambda) \bar{g}(\lambda) d\lambda, \int_{400\text{nm}}^{700\text{nm}} L_e(\lambda) \bar{b}(\lambda) d\lambda \right)$$

3D interpretation of color matching

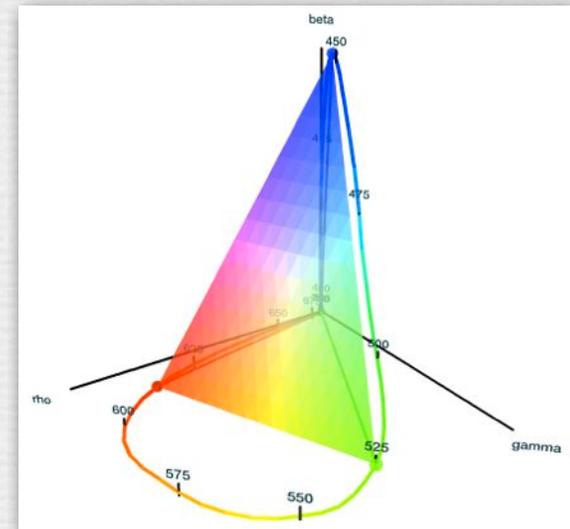

- ◆ our response to varying amounts of a primary forms a vector in (ρ, γ, β) space, rooted at the origin
- ◆ to provide a normal range of color vision, three primaries are required, and their vectors must not lie on a plane
- ◆ our responses to all possible mixtures ($\Sigma \leq 1$) of three primaries form a tetrahedron called the *gamut of reproducible colors* for these primaries

RGB matching functions

(FLASH DEMO)

<http://graphics.stanford.edu/courses/cs178/applets/locus.html>

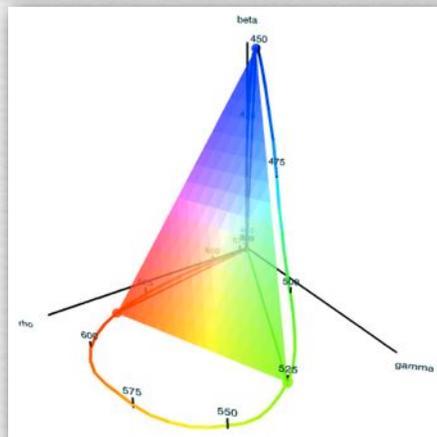

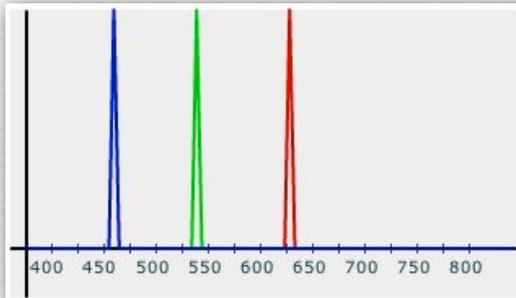

gamut of reproducible colors

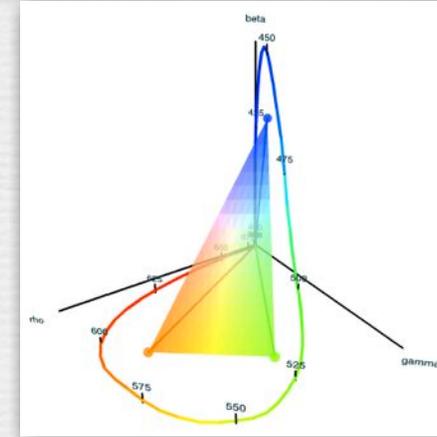

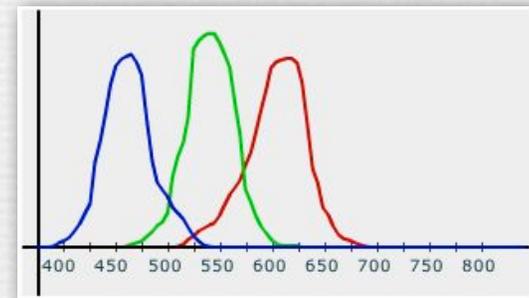

3D interpretation of color matching

- ◆ the spectrum of each of the three primaries can be a pure wavelength (1) or a mixture of wavelengths (2)
- ◆ impure primaries have a smaller gamut in (ρ, γ, β) space
- ◆ additional primaries can be added to increase the gamut

1

2

(FLASH DEMO)

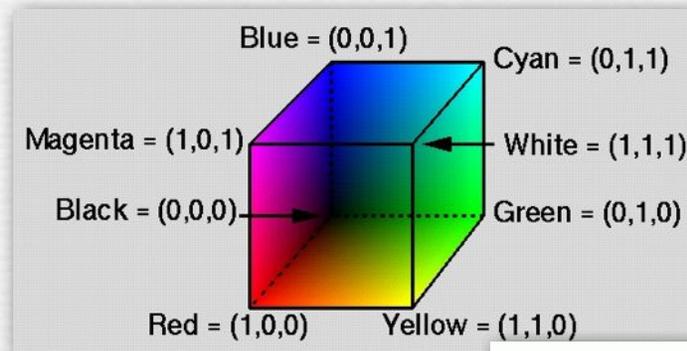

<http://graphics.stanford.edu/courses/cs178/applets/locus.html>

Chromaticity diagrams

- ◆ choose three primaries R,G,B, pure wavelengths or not
- ◆ adjust $R=1,G=1,B=1$ to obtain a desired *reference white*
- ◆ this yields an *RGB cube*

(FLASH DEMO)

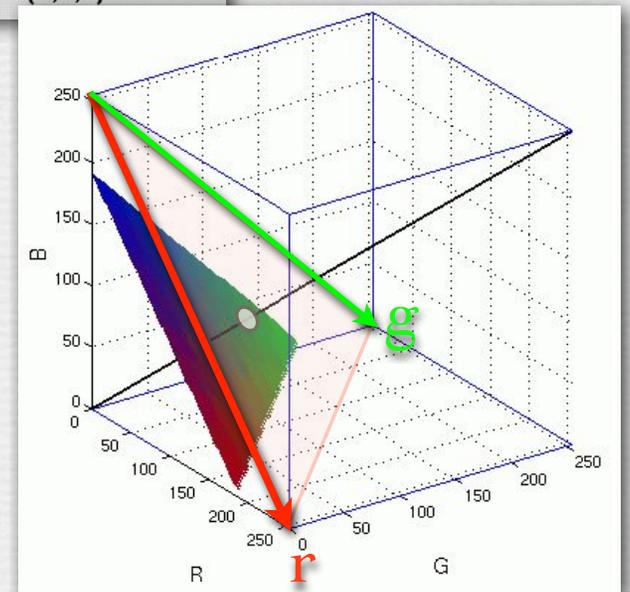

<http://graphics.stanford.edu/courses/cs178/applets/threedgamut.html>

$$r = \frac{R}{R+G+B}$$

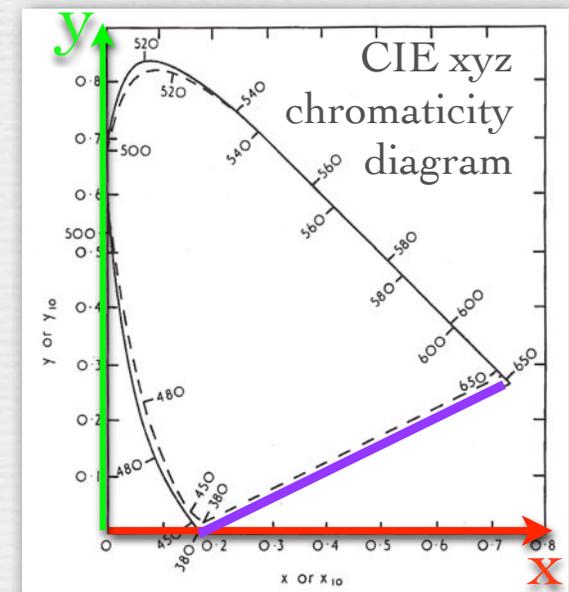

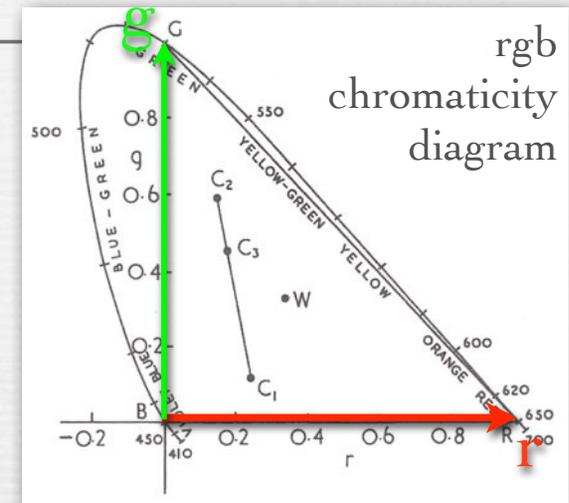

$$g = \frac{G}{R+G+B}$$

- ◆ one may factor the brightness out of any point in the cube by drawing a line to the origin and intersecting this line with the triangle made by corners Red, Green, Blue
- ◆ all points on this triangle, which are addressable by two coordinates, have the same brightness but differing *chromaticity*

Chromaticity diagrams

- ◆ this triangle is called the *rgb chromaticity diagram* for the chosen RGB primaries
 - mixtures of colors lie along straight lines
 - neutral (black to white) lies at $(\frac{1}{3}, \frac{1}{3})$
 - $r > 0, g > 0$ does not enclose spectral locus
- ◆ the same construction can be performed using any set of 3 vectors as primaries, even impossible ones ($\rho < 0$ or $\gamma < 0$ or $\beta < 0$)
- ◆ the CIE has defined a set of primaries XYZ, and the associated *xyz chromaticity diagram*
 - $x > 0, y > 0$ does enclose spectral locus
 - one can connect red and green on the locus with a *line of extra-spectral purples*
 - x, y is a standardized way to denote colors

Learn about the history, manufacture, and technical details of the following pigments, all of which are some of the most historically important in art. Listed alphabetically. Compare colors in 3D using ColoRotate.

Choose a pigment: (Click square to see in 3D. Click name to go to page.)

Azurite	Bone black	Cadmium yellow/red
Carbon black	Carmine	Cerulean Blue
Chrome orange	Chrome yellow	Cobalt blue
Cobalt green	Cobalt violet	Cobalt yellow
Copper resinate	Egyptian blue	Emerald green
Green earth	Indian yellow	Indigo
Lead white	Lead-tin yellow	Lemon yellow
Lime white	Madder	Malachite
Naples yellow	Orpiment	Prussian blue
Realgar	Red lead	Red ochre
Smalt	Titanium white	Ultramarine
Umber	Van Dyke brown	Verdigris
Vermilion	Viridian	Yellow ochre
Zinc white		

AZURITE

Application of chromaticity diagrams #1: standardized color spaces and gamut mapping

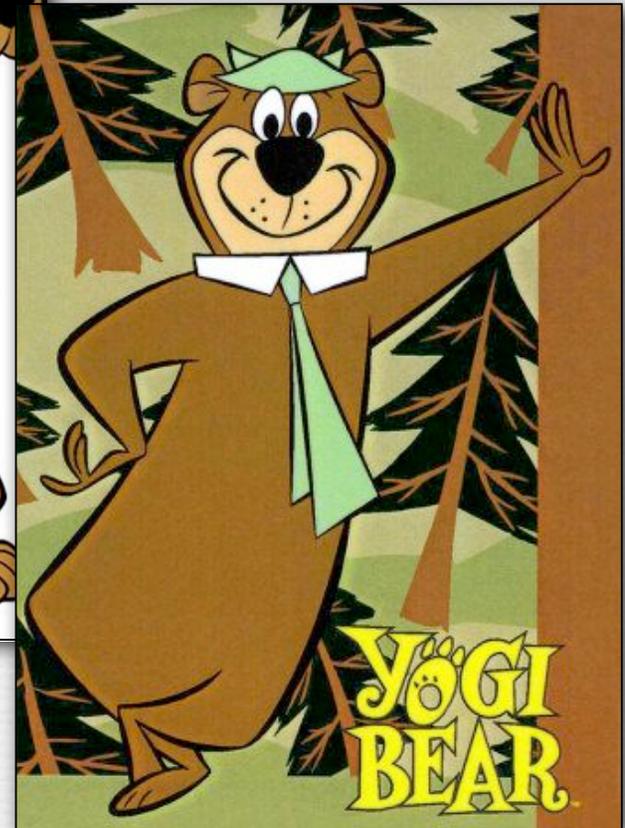

- ◆ the chromaticities reproducible using 3 primaries fill a triangle in the xyz chromaticity diagram, a different triangle for each choice of primaries; this is called the *device gamut* for those primaries

Q. Why is this diagram, scanned from a book, black outside the printer gamut?

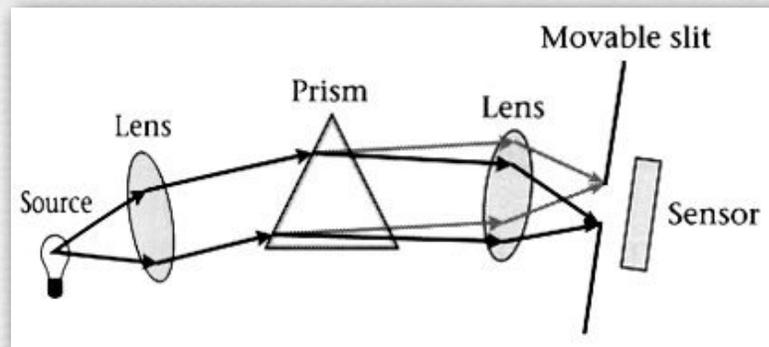

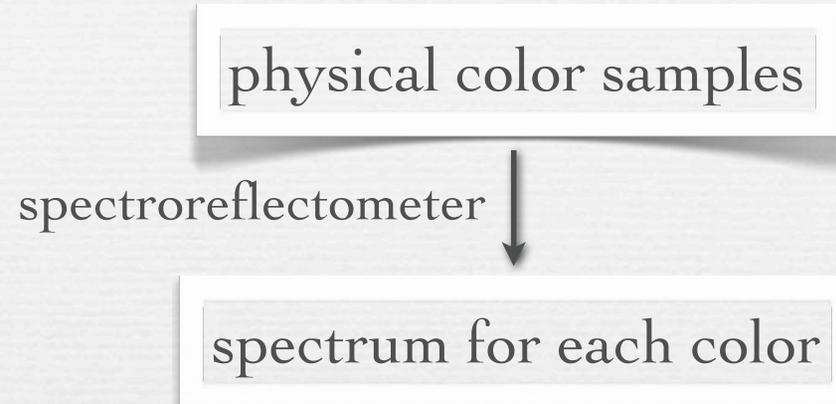

(Foley)

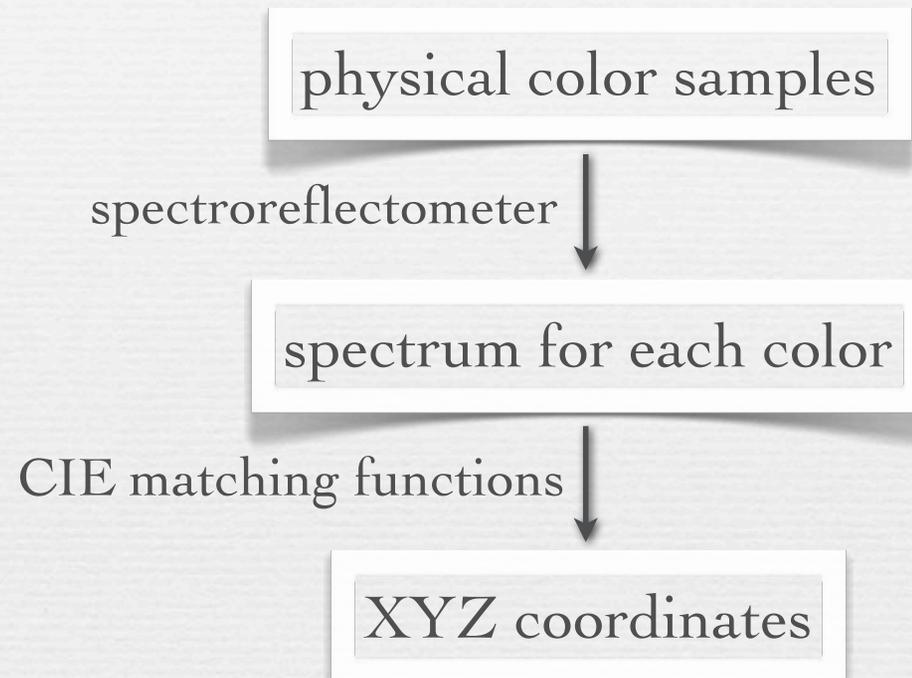

Digitizing the paint colors at Hanna-Barbera Productions

NTSC gamut

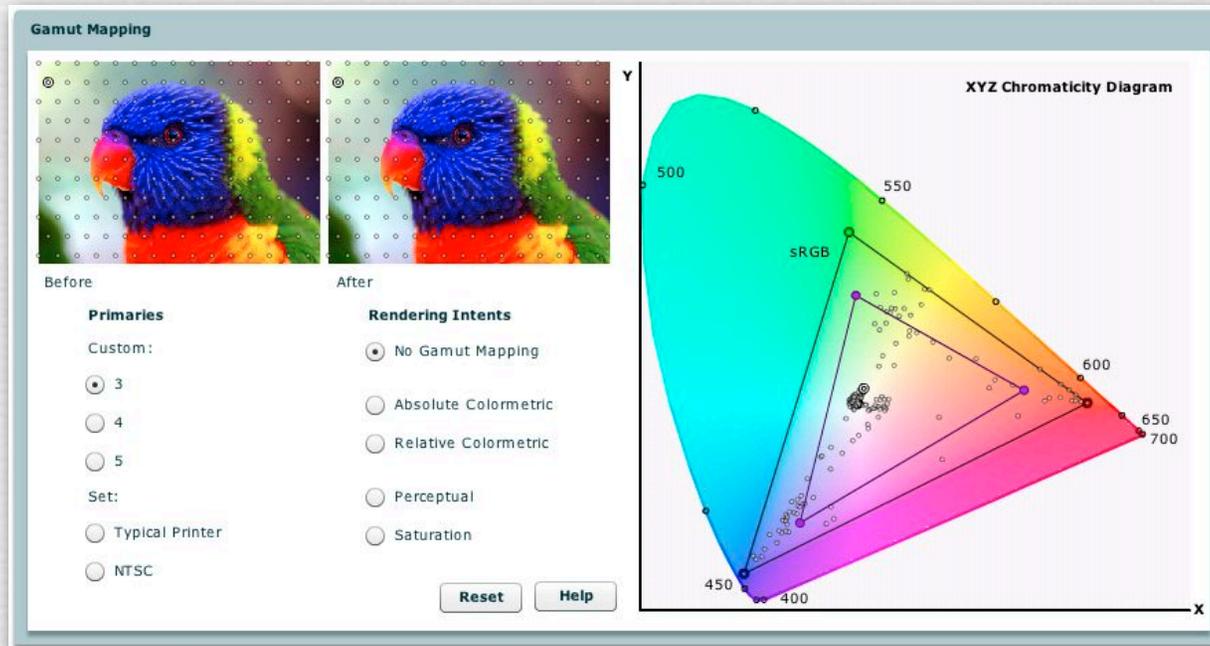

DANGER: NECKTIE OUT OF GAMUT !!

Gamut mapping

you can do this explicitly in Photoshop, or you can let the printer do it for you

◆ called “color space conversion” in Photoshop

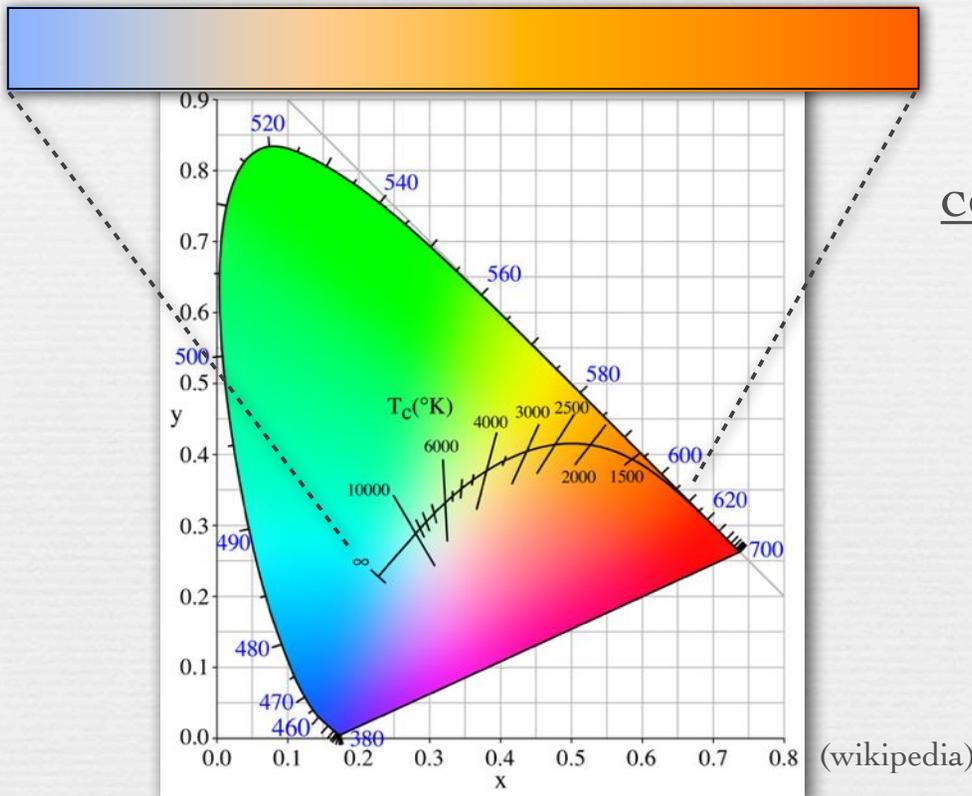

- *relative colorimetric* - shrinks only out-of-gamut colors, towards N
- *absolute colorimetric* - same but shrinks to nearest point on gamut
- *perceptual* - smoothly shrinks all colors to fit in target gamut
- *saturated* - sacrifices smoothness to maintain saturated colors

(FLASH DEMO)

<http://graphics.stanford.edu/courses/cs178/applets/gamutmapping.html>

Application of chromaticity diagrams #2: color temperature and white balancing

correlated color temperatures

3200°K incandescent light

4000°K cool white fluorescent

5000°K equal energy white (D50, E)

6000°K midday sun, photo flash

6500°K overcast, television (D65)

7500°K northern blue sky

(wikipedia)

- ◆ the apparent colors emitted by a *black-body radiator* heated to different temperatures fall on a curve in the chromaticity diagram
- ◆ for non-blackbody sources, the nearest point on the curve is called the *correlated color temperature*

Incorrectly chosen white balance

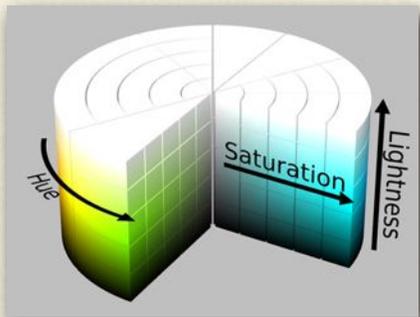

(Eddy Talvala)

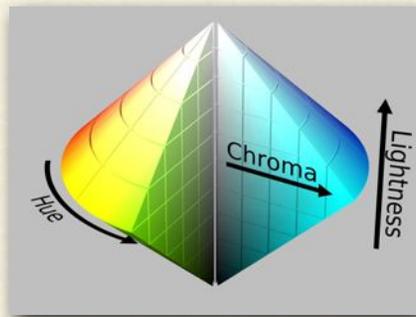

- ◆ scene was photographed in sunlight, but the camera's white balance was set as if the illumination were "warmer", like tungsten
 - white balancer assumed illumination was reddish, so it boosted blues

Cylindrical color spaces

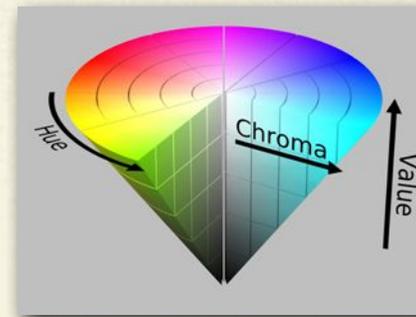

(Wikipedia)

HSL cylinder

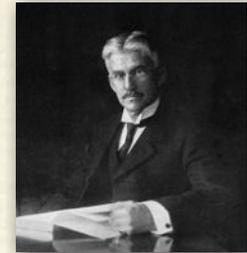

HSL double cone

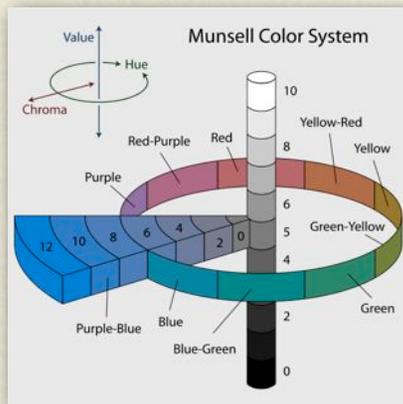

HSV single cone

- ❖ a cylinder is easy to understand, but colors near the top and bottom are indistinguishable
 - * single cone solves this by compressing top & bottom to a point
- ❖ when artists mix “complementary” lights, they expect to get white, but halfway from red to cyan in HSL space is gray
 - * HSV pushes the white point down onto the max-S plane
 - * painters might prefer an inverted cone, with black on this plane

Munsell color system

Albert Munsell
(1858-1918)

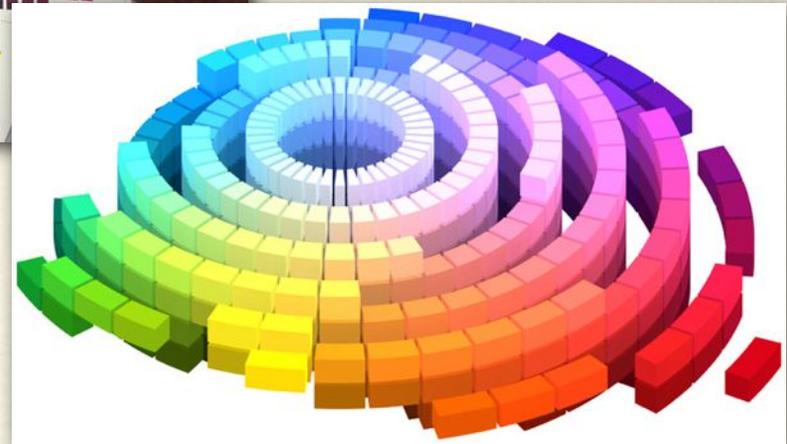

3-axis colorspace

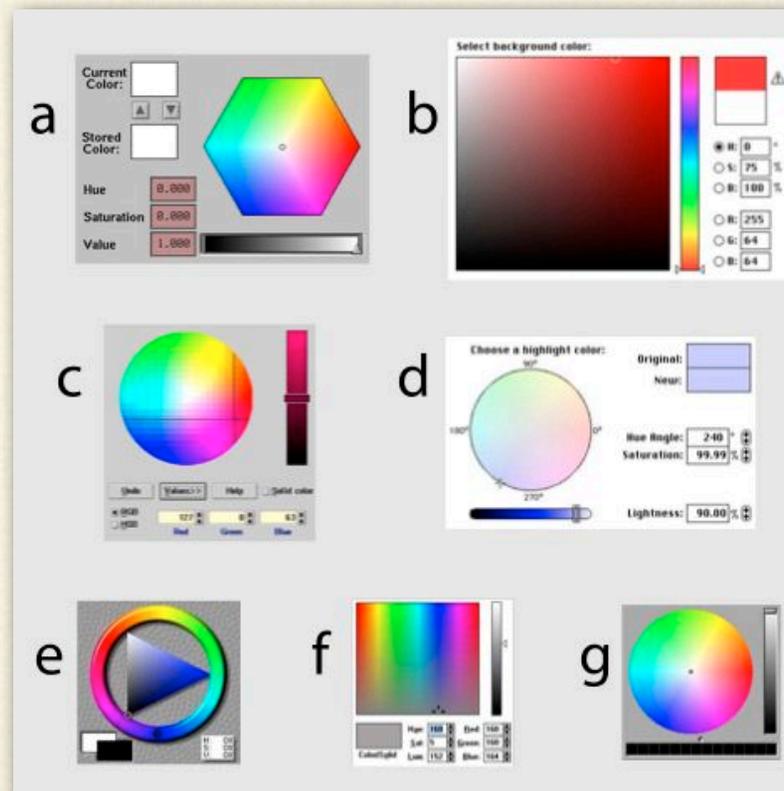

1905 book

CG rendering of
1929 measurements

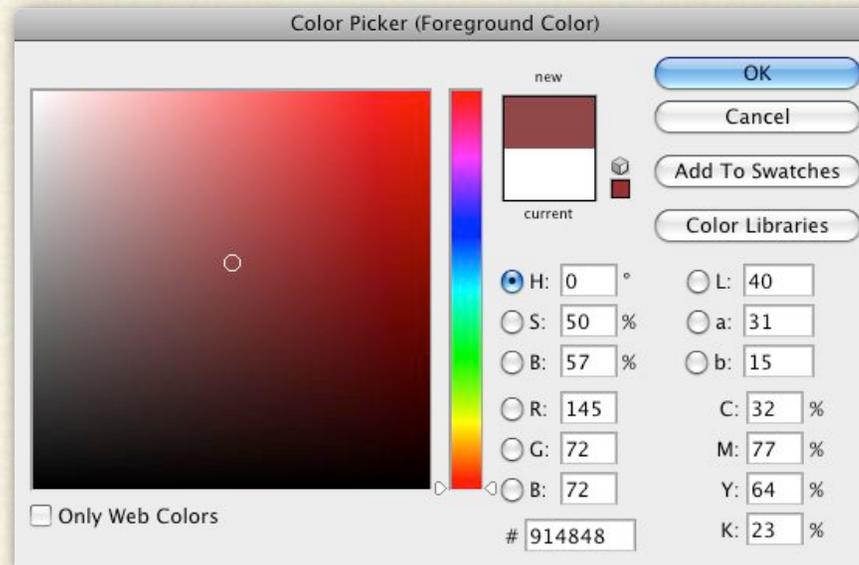

- ❖ spacing of colors is perceptually uniform (by experiment)
- ❖ outer envelope of solid determined by available inks

Opponent colors

Ewald Hering
(1834-1918)

- ♦ observed that humans don't see reddish-green colors or blueish-yellow colors
- ♦ hypothesized three receptors, as shown above

Opponent colors wiring

Practical use of opponent colors: NTSC color television

(wikipedia)

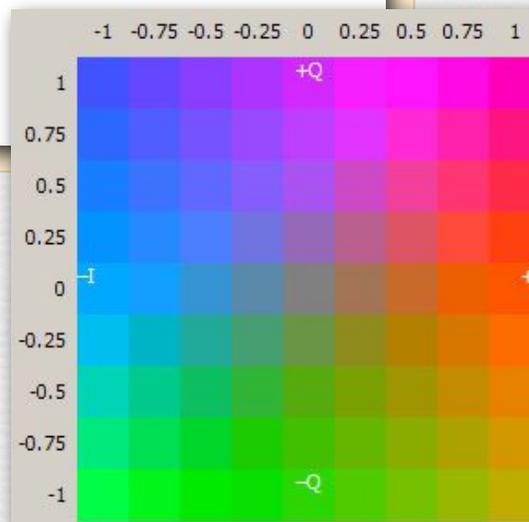

- ◆ color space is YIQ
 - Y = luminance
 - I = orange-blue axis
 - Q = purple-green axis

$$R, G, B, Y \in [0, 1], \quad I \in [-0.5957, 0.5957], \quad Q \in [-0.5226, 0.5226]$$

$$\begin{bmatrix} Y \\ I \\ Q \end{bmatrix} = \begin{bmatrix} 0.299 & 0.587 & 0.114 \\ 0.595716 & -0.274453 & -0.321263 \\ 0.211456 & -0.522591 & 0.311135 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix}$$

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} 1 & 0.9563 & 0.6210 \\ 1 & -0.2721 & -0.6474 \\ 1 & -1.1070 & +1.7046 \end{bmatrix} \begin{bmatrix} Y \\ I \\ Q \end{bmatrix}$$

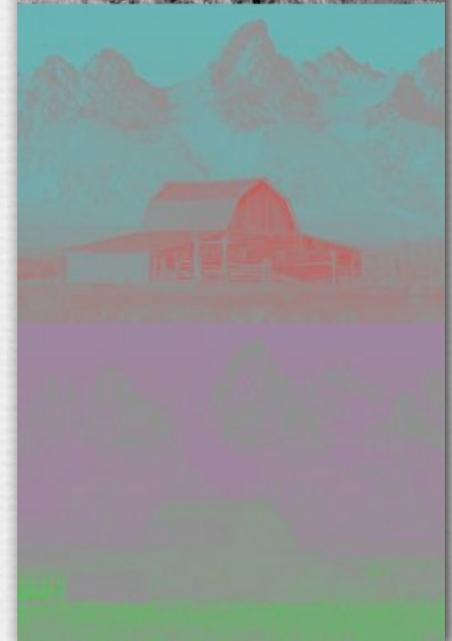

RGB & YIQ are axes in (ρ, γ, β) space, hence these transforms are 3×3 matrix multiplications

Y

I

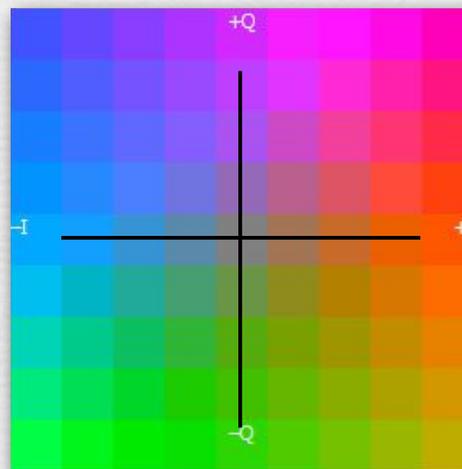

Q

Practical use of opponent colors: JPEG image compression

- ◆ color space is $Y'CbCr$
 - Y' = luminance
 - Cb = yellow-blue axis
 - Cr = red-green axis

$$\begin{aligned} Y' &= 16 + (65.481 \cdot R' + 128.553 \cdot G' + 24.966 \cdot B') \\ C_B &= 128 + (-37.797 \cdot R' - 74.203 \cdot G' + 112.0 \cdot B') \\ C_R &= 128 + (112.0 \cdot R' - 93.786 \cdot G' - 18.214 \cdot B') \end{aligned}$$

(wikipedia)

Y'

Cb

Cr

Practical use of opponent colors: JPEG compression

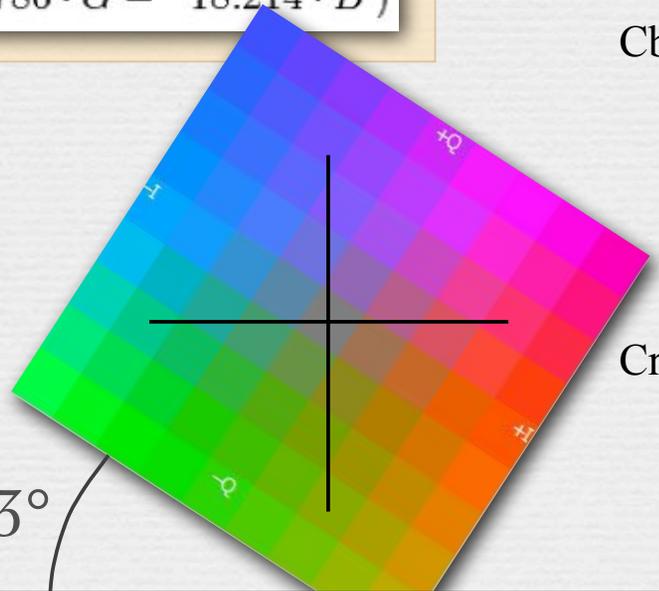

- ◆ color space is YCbCr
 - Y = luminance
 - Cb = yellow-blue axis
 - Cr = red-green axis

we are more sensitive to high frequencies in Y than CbCr, so use more bits for Y (~2x)

$$\begin{aligned}
 Y' &= 16 + (65.481 \cdot R' + 128.553 \cdot G' + 24.966 \cdot B') \\
 C_B &= 128 + (-37.797 \cdot R' - 74.203 \cdot G' + 112.0 \cdot B') \\
 C_R &= 128 + (112.0 \cdot R' - 93.786 \cdot G' - 18.214 \cdot B')
 \end{aligned}$$

inputs R' , G' , B' are R^γ , G^γ , B^γ for some gamma $\gamma < 1$
